ANALYSIS OF SEASONAL AND ANNUAL TRENDS OF
SULPHUR DIOXIDE AS AIR POLLUTANT IN BAREILLY CITY

Abstract
According to a report published by Green Peace (2018), Bareilly city has been reported as one of the most seven polluted cities. Bareilly city do not have too much of industrialization but poor environmental management by the citizens and administration worsen the air quality during Diwali festival. Air monitoring of gaseous pollutant (sulphur dioxide) was done at Bareilly city as per CPCB guidelines from three monitoring stations (A, B and C) for a period of two years (2019-2020). During pre-monsoon season of 2019 all station reported $SO_2$ values below the specified limits of $60 \mu g/m^3$ but station A reported values on the higher side. When lockdown was imposed in March 2020 due to the outbreak of novel corona virus in India and there was significant cut down in $SO_2$. While conducting the two-way ANOVA test for $SO_2$ during both pre-monsoon and post-monsoon seasons from three stations at Bareilly in 2019, it was found that $F>F_{crit}$ and $p-value<0.05$. This paper focuses on the monitoring, analysis and interpretation of $SO_2$ at Bareilly city.

INTRODUCTION
Air pollution isn't restricted to a state, country, region or continent, it could have significant effect on global climate and weather, acid rain issue since the 1970s is a well-aware problem for the world. Formation of acid rain takes place when $SO_2$ and oxides of nitrogen from the burning of excessive fossil fuels combine with the vapour in the atmosphere, forming mist of $H_2SO_4$ and $HNO_3$ that causes damage to water, forest, and soil resources. With the rise in the fossil fuel consumption, CO₂ levels in the atmosphere have increased steadily since 1900, and the rate continues to be on the rise. It has been predicted that if CO₂ levels are not reduced, average global air temperatures may rise another 4 °C (7.2 °F) by the end of the 21st century. This may lead to the melting of the polar ice caps, elevation in the level of sea water, and flooding of the coastal areas globally. Alterations in precipitation patterns caused by climate changes and global warming could cause adverse effects on agriculture and forest ecosystems, and higher temperatures and humidity might increase the incidence of disease in humans and animals in some parts of the earth. Globally we see that in recent decades the death rates from total air pollution have declined: since 1990 the number of deaths per 100,000 people have nearly halved. But, as we see from the breakdown, this decline has been primarily driven by improvements in indoor air pollution. (source, IHME, Global Burden of disease). In a report of WHO, 2018 it has been reported that due to both indoor and outdoor air pollution around seven million people die each year. The three biggest killers attributable to air pollution are stroke (2.2 million deaths), cardiac disease (2.0 million) and lung disease and cancer (1.7 million deaths). Ambient (outdoor) air pollution accounts for: 25 per cent of all deaths and disease from lung cancer, 17 per cent of all deaths and disease from acute lower respiratory infection, 16 per cent of all deaths from stroke 15 per cent of all deaths and disease from ischaemic cardiovascular disease and 8 per...
cent of all deaths and disease from chronic obstructive pulmonary disease. Air pollution doesn't just kill, however. It also contributes to other illnesses, hampers development and causes neurological dis-orderliness. One study found that ambient PM2.5 contributed to more than three million cases of diabetes in 2016. Recent research from the United Nations Children's Fund (UNICEF) shows that inhaling in particulate air pollution can damage brain tissue and undermine cognitive development in young children – with lifelong implications. In India air pollution is very alarming in the current scenario. According to (WHO -2018) and the fourth edition of State of India's Environment (SoE) released on World Environment Day, 5th June 2019 air pollution cause a death toll of an average of around 80 out of every one lakh children in India before they turn five. Urban air quality is deteriorated day by day due to increase in industrialization and urbanization [1, 2]. Population pressure can't be ruled out for a few reason. To satisfy out demand of natural resources are being harvested and transported. The rapid urban growth is also associated with transportation sector and road networks which supports various vehicular movements on roads [3]. Air pollution in India is predominantly caused from three sources namely vehicles [4], industrial and domestic sources. It was reported that air pollutants like NOx and PM concentration (approximately 17% and 28% of total) from vehicular emissions are contributed to the air pollution which was almost equal to the cumulative sources of industry, power plants and domestic sectors in Delhi, India [5]. However, over the last twenty years petrol and diesel consumption have hiked by 400% and 300%, respectively, which was mainly because of rising vehicular numbers, DG sets, industries and waste incinerators [6, 7]. The heavy traffic, thickly populated areas, jams, poor driving patterns, improper town planning and congested and encroached roads have severe impact on the environment in urban areas [1, 8, 9, 10, 11].

Vehicular emissions is associated with a number of chronic and acute health effects [12, 13]. Various studies proved that health issues such as cancers, heart attacks and asthma are associated with NOx, SO, and PM emissions from vehicular exhaust [14, 15]. In urban areas, air pollution is mainly affected due to construction of buildings, traffic composition and meteorological conditions [16]. Air quality models and impact because of pollutant concentration assessment studies provide a tool to better understand the implications of pollutant emissions which could help us to decide, control and manage the environmental pollutions [17]. Air pollutant dispersion modeling has been accomplished with the aid of Gaussian Dispersion Plume models that, accounted for the spatial and temporal dispersion characteristics of various pollutants. However, line source models are generally used to assess the effects of roadway emissions and dispersion of the pollutants [18, 19]. Traffic estimation studies can either be done by on-site traffic counting (manually or installing CCTV camera or counter devices) [20, 21, 22], or derived from travel demand and traffic simulation models [23, 24, 25]. Emissions are often estimated considering average link speeds and average emission factors [20, 22, 23, 25] or real-time link drive-cycles [24]. Airborne particulate matter (PM) is a type of a colloid solution composed of small droplets of liquid, dry solid fragments, and solid cores with liquid coatings. PM particles are not a single pollutant, instead it is a mixture of different chemical species. Therefore, PM2.5 comprises a portion of PM10. The primary source of Particulate matter is from anthropogenic activities such as burning of fossil fuel, vehicular emissions, road dust suspensions, wear out of brakes and tyres, ash from industries as well as incomplete construction work. Exhaust traffic related particles have been identified as a major contributor to ambient PM. Vehicular emissions are one of the major sources of outdoor air pollution in major cities of India. The number of vehicles on road has increased non-linearly over the past two decades has resulted in high levels of air pollution. In most of the major cities/towns there has been uncontrolled growth of vehicle population. High vehicle density in Indian urban centers results in air pollution buildup near the roadways and at traffic intersections. Older vehicles are predominant in vehicle vintage. Older vehicles release more air pollutants hence vehicles older than 15 years of registration are now phased out and cannot move on roads in Delhi. But, in small cities still old vehicles are being operated on roads without a stringent check. Inadequate inspection and maintenance facilities result in high emission of air pollutants from vehicles. In order to reduce the emission of particulate matter and gaseous pollutants, regular inspection and maintenance of vehicles should be done. Also, vehicles in India easily get Pollution Under Control certificate. According to the Society of Indian Automobile Manufacturer (SIAM) (Table 1) automobile sale trend was studied over a period of five years as shown in the table below:

Day by day the air quality which we are inhaling is being detoriated and getting even worsen. It has been found and reported that around ten million people from India[31] lose their lives due to air pollution. Around 30% of cardiac patient are affected due to air pollution[32]. School going children and new born babies are suffering from emphysema. Also senior citizen are suffering from breathlessness due to emission of pollutant. Hence a serious monitoring, analysis and remedial steps need to be taken in this regards. CPCB and also media reported that Bareilly [Figure 1] was thickly polluted and in UP the third most polluted city.

There are more than 30 fuel pumps in Bareilly city [Figure 2] and due to large population there is huge consumption of fuel in the entire city.

- **Ab** = Absorbance of reagent blank
- **CF** = Calibration factor
- **Va** = Volume of air sampled, m³
- **Vs** = Volume of sample, ml
- **Vt** = Volume of aliquot taken for analysis, ml
This paper focuses on the data organization of gaseous air pollutant \( \text{SO}_2 \) from three monitoring stations of Bareilly district. The air monitoring was carried out at the following three stations at Bareilly district. The field data obtained was recorded and analysed in the laboratory. All data obtained during the year 2019 during field research was organized, analysed, interpreted and represented in the form graphs and tables for better analysis and evaluation. Following are the monitoring stations /location [Figure 3] from where the air pollutants have been sampled for analysis.

**Results and Discussions**

The collection of data was done as per the CPCB guideline and methods were followed as discussed in chapter three. Table represents monthly average concentrations of \( \text{SO}_2 \) pollutants in \( \mu g/m^3 \) from three stations A, B and C respectively. The first six months of the year i.e. January 2019 to June 2019 are studied as Pre-monsoon season and from July 2019 to December 2019 are studied under Post Monsoon season.

**Table 2:** \( \text{SO}_2 \) data during Pre-monsoon and Post monsoon in 2019 from three stations.

**PREMONSOON TRENDS OF \( \text{SO}_2 \)**

During the Pre-monsoon season, as can be seen from the following figure that all stations reported \( \text{SO}_2 \) concentration are below the maximum permissible limit of 60 \( \mu g/m^3 \) according to NAAQS. Station A, located on the highway, is considered to be heavy traffic site, where as station C being a residential site was considered to be control site or low traffic site. Station B is commercial cum residential site. The green worm in the following figure corresponds to station C which lies always below the curves corresponding to station A and station B during the entire pre-monsoon season. No regular trend is observed during the pre-monsoon season but the values remained below the maximum allowable limits.

**Figure 4:** Pre-monsoon trends of \( \text{SO}_2 \) during 2019.

**Post-monsoon comparative data for \( \text{SO}_2 \)**

During the post- monsoon season all station show an increasing trends till the month of November 2019 in the values of \( \text{SO}_2 \) concentration. As expected, the low vehicular site, Station C, reported the least value of \( \text{SO}_2 \) concentration during the entire post monsoon season.
ANNUAL TRENDS (Pre and Post Monsoon)
OF SO\textsuperscript{2} FOR THE YEAR 2019

Bareilly city do not have too much of industries emitting gaseous pollutants. The only major source of gaseous pollutant in the city is vehicular emissions, which can be verified from the annual trend analysis of SO\textsuperscript{2} levels at the three air monitoring sites. Station A showed relatively large values of SO\textsuperscript{2} as it is located on highway and is a heavy vehicular site. During the entire 2019 all stations reached their individual peak value only the month of November 2019 which is possibly due to the emission from fire crackers burned during Diwali festival.

The gaseous pollutants studied during the course of research was SO\textsuperscript{2}. Bareilly city do not have too much of industrialization. SO\textsuperscript{2} level were found to be less than the maximum allowable limits [Figure 3] when measured from the three air monitoring sites. For all the stations A, B and C respectively, the post-monsoon average has relatively higher SO\textsuperscript{2} concentration in comparison to the pre-monsoon average.

While conducting the two way ANOVA test for SO\textsuperscript{2} during both pre-monsoon and post-monsoon seasons from three stations at Bareilly in 2019, it was found that F>F crit. and p-value<0.05 [Table 3] for both seasons and monitoring stations. This signifies that there is significant variation in mean value of gaseous pollutant (SO\textsuperscript{2}) during pre and post monsoon season. Also, the three monitoring locations have an appreciable difference in their mean values during pre and post monsoon.

**Conclusions**

A large number of health issues have been reported which are predominantly due to poor ambient air quality. From the analysis of the gaseous air pollutant SO\textsuperscript{2} for the year 2019 from three monitoring locations depending on the traffic frequency in the vicinity of 11 km, it can be concluded that the concentration of gaseous air pollutant SO\textsuperscript{2} in Bareilly city measured from station A were alarming during the winter season and were on the higher side in comparison to the other two stations B and C. Bareilly city do not have too much industrialization and hence emission of gaseous air pollutant sulphur dioxide largely depends on vehicular emissions which is evident from the sale of diesel and petrol fuel reported from the fuel pumps in the study area[26]. As expected, the Station A being a commercial and heavy traffic site showed SO\textsuperscript{2} relatively higher concentration of SO\textsuperscript{2} whereas station C being a residential site recorded much lower SO\textsuperscript{2} values. Thus, it can be concluded that the possible cause of air pollutant PM2.5 in the city Bareilly could be vehicular emissions. The study carried out for air pollutant analysis is from a limited number of stations covering only an area of 11 km. On increasing the number of monitoring locations better estimate of air quality can be done. Currently, low attention is given to air pollution in spite that millions die due to air pollution all over the world. Air pollution should be thoroughly understood by developing countries and should be given priority. Long-term exposures to gaseous pollutants (up to 24-hours duration) are found to be associated with premature mortality, increased hospital admissions for heart or lung causes, acute and chronic bronchitis, asthma attacks, emergency room visits, respiratory disorders, and restricted activity days. Health of new born babies, children, and older adults with an existing history of heart or lung diseases are found to adversely effected. Health issues due to long-term (months to years) exposure to PM2.5 has been linked to premature death, particularly in patients who already have preexisting chronic heart or lung diseases, and reduced lung function growth in infants. In 2015 a review was published in the International Agency for Research on Cancer (IARC) that concluded that outdoor air pollution causes lung cancer [28]. WHO's IARC[29] have reported exhaust emission, particularly diesel exhaust, as deemed carcinogenic. Non-exhausted emission of traffic-related pollutants, wear out of...
tyre and brakes contributes as much and often more than tailpipe exhaust to the ambient outdoor air pollutants concentrations in cities [27] but no such conclusions have been made in this regard. The increasing level of gaseous pollutants such as SO in tir two cities such as Bareilly could be alarming and may pose serious health hazards to the human health.
